

RRSP 50k CAD Deployment Plan (v1)

Date (ET): 2026-02-08

Disclaimer: This is research + portfolio-structure coaching, not financial advice. You make the final decision.

Your constraints (locked)

- Objective: **Growth**
- Horizon: **6–12 months**
- Max drawdown tolerance: **~10%** (tight)
- Rule: **Never sell NVDA**
- Portfolio lens: **Combined** (TFSA + RRSP together)
- Preference: **Option B** (growth tilt)

Default assumptions (because you said “not sure”)

If you don't specify otherwise, the safest “growth-tilt but controlled” default is: - Put **most** of the 50k into **broad ETFs** (simple, diversified) - Use **CAD-listed ETFs** where possible to reduce friction (FX + complexity) - Deploy in **tranches** to reduce timing risk

If any of these assumptions are wrong, tell me and I'll regenerate.

1) Execution plan (tranches)

Do **not** invest all 50k on the same day.

Tranche schedule (1 month): - **T1:** 20k CAD now - **T2:** 15k CAD in ~2 weeks - **T3:** 15k CAD in ~4 weeks

Drawdown guardrail (simple): - If the combined portfolio drawdown hits **-7%**, pause T2/T3 and re-check. - If drawdown hits **-10%**, stop adding risk; prioritize stabilization.

2) Allocation blueprint (ETF-heavy, growth tilt)

Because you already have NVDA and a lot of US mega-cap exposure, the key is to **avoid accidental double/triple exposure** through overlapping ETFs.

Option B (ETF-heavy) — recommended starting point

Target split for the 50k contribution: - **80% core ETFs** (40k CAD) - **20% satellites** (10k CAD)

Core ETFs (choose 1 lane for US equity + 1 diversifier) Pick **one** primary lane to avoid overlap: - **Lane 1 (S&P 500 CAD):** VFV (CAD S&P 500) or equivalent - **Lane 2 (Nasdaq-100 CAD):** QQC / XQQ (CAD Nasdaq exposure)

My default suggestion (given “NVDA never sell”): - Prefer **S&P 500 lane** as the core (VFV/SP500), and let NVDA be your growth concentration. - Add a **broad global/Canada diversifier** only if you want smoother drawdowns (XEQT or a Canada dividend ETF). This depends on how strict that 10% drawdown budget is.

Satellites (small, controlled)

- Semiconductor ETF (SOXX or CAD equivalent) **only if** you are comfortable with the AI/semis concentration. Otherwise, skip.
 - A single “quality growth” ETF can replace multiple single stocks.
-

3) What to do with existing overlaps (no forced selling)

Instead of selling immediately, we use **new money routing**: - If you already own **multiple** of (SPY/VFV) *and* (QQC/XQQ/QQQM) *and* MGK, then for the RRSP deposit: - Route new money to **ONE** primary index lane (S&P500 or Nasdaq100), not both. - Avoid adding more mega-growth wrappers (MGK) unless it's your only wrapper.

This reduces overlap over time with minimal taxes/friction.

4) Risk notes specific to your portfolio

- **Theme concentration:** NVDA + Nasdaq + semis ETF is a high-beta cluster. Option B can work, but respect position sizing.
 - **Speculative bucket:** keep high-vol single names (small caps / quantum / story stocks) capped (e.g., **<=5% total**) to protect the 10% drawdown constraint.
 - **CAD vs USD:** If you convert to USD, you gain flexibility; if you stay CAD ETFs, execution is simpler. Both are fine—pick one and standardize.
-

5) What I need from you (2 answers) to finalize exact tickers + % per tranche

Reply with: 1) **Core lane:** S&P500 (VFV/SPY-style) or Nasdaq100 (QQC/XQQ-style) or both? 2) **FX preference for RRSP:** keep it CAD ETFs, or convert part to USD?

Once you answer, I'll generate v2 with: - exact % per tranche - list of “don't buy more of these” (overlap control) - daily brief watchlist derived from your largest exposures
